

Constants and Arithmetic

Declare a value once in front-matter, reference it anywhere with `{{ name }}`, and derive the rest with arithmetic. Change the rate in one place and every figure below follows.

Rates

Component	Rate	Note
Day rate	3 000 NOK	Per 24-hour period
Hourly	290 NOK	Full qualification
Hourly	275 NOK	Reduced
Per diem	400 NOK	Per night

Derived figures

Overtime is a multiplier on the hourly rate, so it is never written down literally:

Overtime	Supplement	Total
50%	+145	435 NOK/h
100%	+290	580 NOK/h

Worked examples compute from the same source:

Case	Calculation	Amount
14 hours	14×290	4 060 NOK
5 days	$5 \times 3\,000$	15 000 NOK
A week away	$5 \times (3\,000 + 400)$	17 000 NOK

The `constants_locale: nb-NO` setting is what groups those digits — without it they render bare.

Expressions

Supported: `+`, `-`, `*`, `/`, `%`, parentheses and unary minus, over numbers and constant names.

- Half of a day rate: 1 500
- Rounded to two decimals by default: 428,57
- Precedence works as expected: 1 380

Escaping

Placeholders inside code are left alone — `{{ hourly_rate }}` renders literally, as does this block:

```
constants:
  hourly_rate: 290
```

Outside code, escape the opening braces with a backslash: `{{ hourly_rate }}`.
